## 1 Revision of Groups

### Definition 1.3.10: Order of an Element

Let  $g \in G$ . The **order** of  $g$ , written  $o(g)$ , is the least positive integer s.t.  $g^n = e$ , or  $\infty$  if  $n$  does not exist. Note that  $o(g) = |\langle g \rangle|$ .

### Theorem 1.3.8: Lagrange’s Theorem

Let  $H$  be a subgroup of a finite group  $G$ . Then the order of a subgroup divides the order of a group, i.e.

$$|G| = [G : H] \cdot |H|$$

### Theorem 1.3.9: Cauchy’s Theorem

If  $G$  is a finite group and  $p$  is a prime that divides the order of  $G$ , then  $G$  has a subgroup of order  $p$ .

### Corollary 1.3.11: Prime Cyclic Groups

If  $|G|$  is prime, then  $G$  is cyclic.

### Definition 1.4.A: Morphisms

Let  $G, H$  be groups.

#### Definition 1.4.1: Group Homomorphism

A function  $\phi : G \rightarrow H$  such that  $\phi(ab) = \phi(a)\phi(b)$  for all  $a, b \in G$  is a **group homomorphism**.

#### Definition 1.4.3: Group Isomorphism

A bijective group homomorphism  $\psi : G \rightarrow H$ ,  $\psi$  is a **group isomorphism** and  $G$  and  $H$  are isomorphic.

If  $p$  is prime, all groups of order  $p$  are isomorphic.

#### Definition 1.4.6: Group Automorphisms

The **Automorphism group** of  $G$ ,  $\text{Aut}(G)$ , is the set of all isomorphisms  $\phi : G \rightarrow G$ . The operation is composition of functions.

### Example 1.4.2: The Cyclic Group $C_n$

The **cyclic group of order  $n$** , written  $C_n$ , can be thought of the set of rotations by  $2\pi/n$  of an  $n$ -gon.

### Definition 1.4.5: Kernel of a Homomorphism

Let  $\phi : G \rightarrow H$  be a group homomorphism. The **kernel** of  $\phi$  is

$$\{g \in G \mid \phi(g) = e\}.$$

A group homomorphism  $\phi$  is injective iff  $\ker \phi = \{e\}$

### Definition 1.4.8: Product Group

Let  $G, H$  be groups. The **product**, or **direct product**,  $G \times H$  is a group, with group operation  $\star$  given by

$$(g, h) \star (g', h') = (g \star_G g', h \star_H h')$$

Note: we usually just say  $(g, h) \star (g', h') = (gg', hh')$

If  $\gcd(m, n) = 1$ , then  $C_m \times C_n \cong C_{mn}$ .

### Theorem 2.1.1: Normal Subgroups and Kernels

Let  $G$  be a group and  $M \leq G$ . Then  $N \triangleleft G$  iff  $N$  is the kernel of a group homomorphism from  $G$  to another group  $H$ .

Suppose  $N \triangleleft G$ . We want a group  $H$  and homomorphism  $\alpha : G \rightarrow H$  with kernel  $N$ . Let  $H$  be the **factor group**  $G/N$ , or

$$G/N = \{(\text{left or right}) \text{ cosets of } N\}$$

We can show...

1. There is a **natural** way to make  $G/N$  a group
2. There is a **canonical** group homomorphism  $\text{can} : G \rightarrow G/N$
3.  $\ker(\text{can}) = N$

### Theorem 2.2.1: First Isomorphism Theorem for Groups

If  $\phi : G \rightarrow H$  is a group homomorphism,  $N := \ker(\phi)$  is a normal subgroup of  $G$ ,  $\text{Im}(\phi)$  is a subgroup of  $H$ , and there is an isomorphism

$$\bar{\theta} : G/\ker(\theta) \xrightarrow{\cong} \text{Im}(\theta)$$

defined by  $\bar{\theta}(gN) = \theta(g)$ . If  $\theta$  is surjective, then  $G/\ker(\phi) \cong H$ .

### Theorem 2.2.3: Universal Property of Factor Groups

For a group  $G$ , and  $N \triangleleft G$ , for any homomorphism  $\psi : G \rightarrow H$  with  $N \subseteq \ker(\psi)$ , there is a unique homomorphism  $\bar{\psi} : G/N \rightarrow H$  s.t.  $\bar{\psi} \circ \text{can} = \psi$ , where  $\text{can} : G \rightarrow G/N$  is the canonical homomorphism.

### Corollary 2.2.4

If  $\phi : G \rightarrow K$  is a surjective group homomorphism, and  $\phi : G \rightarrow H$  is a group homomorphism with  $\ker(\phi) \subseteq \ker(\psi)$ , then there is a unique group homomorphism  $\bar{\psi} : K \rightarrow H$  such that  $\bar{\psi}\phi = \psi$ .

### Proposition 2.3.1: Canonical Pullbacks

Let  $G$  be a group and let  $N \triangleleft G$ . Let  $\text{can} : G \rightarrow G/N$  be the canonical map. Let  $K \leq G/N$ .

1.  $\text{can}^{-1}(K) \leq G$  with  $N \subseteq \text{can}^{-1}(K)$ .
2.  $\text{can}^{-1}(K) \triangleleft G$  if and only if  $K \triangleleft G/N$

### Proposition 2.3.2

Let  $N \triangleleft G$  and let  $\text{can} : G \rightarrow G/N$  be the canonical map. If  $N \leq H \leq G$ , then  $H = \text{can}^{-1}(\text{can}(H))$ . That is, all subgroups of  $G$  that can contain  $N$  are “pulled back” from subgroups of  $G/N$ .

### Theorem 2.3.3: Correspondence Theorem

Let  $G$  be a group,  $N \triangleleft G$ , and let  $\text{can} : G \rightarrow G/N$  be the canonical map. The map  $H \mapsto \text{can}(H)$  is a bijection between subgroups of  $G$  containing  $N$  and subgroups of  $G/N$ . Under this bijection, normal subgroups match with normal subgroups. Further, if  $N \subseteq A, B$  are subgroups of  $G$ , then  $\text{can}(A) \subseteq \text{can}(B)$  iff  $A \subseteq B$ .

### Example 2.3.4: Correspondence Example

Find all subgroups of  $\mathbb{Z}/12 = \mathbb{Z}/12\mathbb{Z}$  together with their inclusions.

The subgroups of  $\mathbb{Z}$  that contain  $12\mathbb{Z}$ :

Via The Correspondence Thm, the subgroups of  $\mathbb{Z}/12$ :

### Theorem 2.3.5: Third Isomorphism Theorem

If  $N \leq H \leq G$  with  $N, H \triangleleft G$ , then

$$(G/N)/(H/N) \cong G/H$$

### Theorem 2.3.7: Second Isomorphism Theorem for Groups

Let  $N$  be a normal subgroup of a group  $G$ , and  $H$  be a subgroup of  $G$ .

- a)  $HN$  is a subgroup of  $G$
- b)  $N \triangleleft HN$
- c)  $H \cap N \triangleleft H$
- d) There is an isomorphism  $HN/N \cong H(H \cap N)$

3 Group Presentations

Definition 3.1: Multiplication Table

We can record group structures with a <b>multiplication table</b> .		$g_1$	$g_2$	$\cdots$	$g_n$
	$g_1$	$g_1^2$	$g_1g_2$	$\cdots$	$g_1g_n$
	$g_2$	$g_2g_1$	$g_2^2$	$\cdots$	$g_2g_n$
	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$

Example 3.2.1: A Simple Group Presentation

Let  $n \in \mathbb{Z}_{\geq 1}$ . We'll define a new group  $A$ , which we write  $A = \langle x \mid x^n = e \rangle$

The notation means “ $A$  is the group generated by  $x$ , subject to the group axioms, the rule  $x^n = e$ , and all logical consequences”.

The elements of  $A$  are  $\{x, x^2, x^3, \dots, x^{n-1}, x^n = e\}$ . i.e.e  $A \cong C_n$ .

Definition 3.2.2: Free Group

The **free group on generators**  $x_1, x_2, \dots, x_m$ , written  $\langle x_1, \dots, x_m \rangle$ , is the group whose elements are words in the symbols  $x_1, \dots, x_m, x_1^{-1}, \dots, x_m^{-1}$  subject to the group axioms and all logical consequences. The group operation is concatenation.

Definition 3.2.3: Group Presentation

Let  $r_1, \dots, r_n \in \langle x_1, \dots, x_m \rangle$ . The group **generated** by  $x_1, \dots, x_m$  subject to the **relations**  $r_1, \dots, r_n$  is the group with generators  $x_1, \dots, x_m$ , subject to the rules that  $r_1 = r_2 = \dots = r_n = e$ , the group axioms, and all logical consequences. This group is written  $\langle x_1, \dots, x_m \mid r_1, \dots, r_m \rangle$

This notation gives a **presentation** of the group

Example 3.2.A: Examples of Free Groups

**Example 3.2.4:** Let  $B = \langle x \mid - \rangle$  (Here, the  $-$  means there are no relations).  $B$  is the free group on the generator  $x$ . Writing out the elements of  $B$  we get  $B = \{ \dots, x^{-3}, x^{-2}, x^{-1}, e, x, x^2, x^3, \dots \}$ . The map  $x^a \mapsto a$  gives an isomorphism between  $B$  and  $\mathbb{Z}$ .

**Example 3.2.5:** Let  $C = \langle x, y \mid xyx^{-1}y^{-1} \rangle$ . In  $C$ , we have  $xyx^{-1}y^{-1} = e$ , so  $xy = yx$ . Therefore an element of  $C$  is a product of some  $x$ 's then some  $y$ 's. i.e.  $C = \{x^a y^b \mid a, b \in \mathbb{Z}\}$ , i.e.  $C \cong \mathbb{Z} \times \mathbb{Z}$

**Example 3.2.6:** Let  $D = \langle x \mid x^3 = x^2 \rangle$ . Since we can use group axioms, and logical consequences, we have the cancellation property.

$$x^3 = x^2 \implies x = e \implies D = \{e\}.$$

Theorem 3.2.7: Novikov’s Theorem

There is no algorithm for deciding whether or not  $\langle x_1, \dots, x_m \mid r_1, \dots, r_m \rangle = \{e\}$

Example 3.2.8: E

Let  $E = \langle a, b \mid a^2, b^5, (ab)^5 \rangle$ . Notice that in  $E$ , we have  $abab = e = b^5 \implies aba = b^5 \implies ba = a^2ba = ab^4$

Note: the equation  $ba = ab^4$  gives us..

**Lemma 3.2.10:** Any element  $x \in E$  can be written  $x = a^i b^j$ , where  $i \in \{0, 1\}$  and  $j \in \{0, 1, 2, 3, 4\}$

Proposition 3.2.11: Universal Property of Free Groups

For a group  $G$  generated by a set  $\{s_1, \dots, s_n\}$ , let  $F = \langle S_1, \dots, S_n \rangle$  be the free group on the letters  $\{S_1, \dots, S_n\}$ . Then there is a unique surjective homomorphism from  $\pi : F \rightarrow G$  s.t.  $\pi(S_i) = s_i$  for all  $i$ .

Example 3.2.12: Dihedral Presentation

We have  $\langle a, b \mid a^2, b^n, (ab)^2 \rangle \cong D_n$  for any  $n \geq 3$ .

4 Sylow Theorems

Definition 4.1.1:  $p$ -subgroup

Let  $G$  be a finite group and let  $p$  be a prime. A subgroup  $H$  of  $G$  is a...

- $p$ -subgroup** of  $G$  if it has order  $p^n$  for some  $n$
- Sylow  $p$ -subgroup** if its order is the highest power of  $p$  that divides the order of  $G$
- Sylow subgroup** of  $G$  if it is a Sylow  $p$ -subgroup for some  $p$ .

Theorem 4.1.A: Sylow Theorems I - III

Let  $|G| = n$  and suppose that  $p$  is a prime that divides  $n$ . Write  $n = p^m r$  with  $p$  not dividing  $r$ .

Theorem 4.1.2: Sylow I

Then there exists at least one subgroup of order  $p^m$ . That is, there is at least one Sylow  $p$ -subgroup.

Theorem 4.1.3: Sylow II

Suppose that  $P$  is a Sylow  $p$ -subgroup and that  $H \leq G$  is any  $p$ -subgroup of  $G$ . Then there exists  $x \in G$  with  $H \subseteq xPx^{-1}$ . In particular, any two Sylow  $p$ -subgroups of  $G$  are conjugate in  $G$ .

Theorem 4.1.4: Sylow III

Let  $n_p$  be the number of distinct Sylow  $p$ -subgroups of  $G$ . Then  $n_p \mid r$  and  $n_p \equiv 1 \pmod p$

Example 4.1.B: Elementary Sylow Subgroups

**Example 4.1.5: Sylow Subgroups of  $S_3$ :**  $|S_3| = 6$  therefore the possible nontrivial Sylow  $p$ -subgroups would be of order 2 and 3.

- There are three transpositions in  $S_3$  and we get three Sylow 2-subgroups of order 2. They are all conjugate, since all transpositions in  $S_n$  are conjugate.
- There is a unique subgroup of order 3, which is normal

**Example 4.1.6: Sylow Subgroups of  $D_6$ :**  $|D_6| = 12$ , therefore Sylow I predicts subgroups of order 3 and subgroups of order 4. Let  $g$  be a reflection and  $h$  the clockwise rotation by  $\pi/3$ .

- $h^2$  generates a subgroup of order 3, and since all elements of  $D_6$  that are not powers of  $h$  are reflections, this is the only one.
- $D_6$  has no elements of order 4, so a Sylow 2-subgroup must be isomorphic to  $C_2 \times C_2$ . In  $D_6$  we have  $ah^3 = h^3a$  for any reflection  $a$ .
- So  $\{e, a, h^3, ah^3\}$  is a subgroup of  $D_6$  for any reflection  $a$ . If  $a$  is a reflection, then  $a = gh^i$  for some  $i$ . We see that there are 3 Sylow 2-subgroups of  $D_6$ :

$$\{e, g, h^3, gh^3\}, \{e, gh, h^3, gh^4\}, \{e, gh^2, h^3, gh^5\}.$$

These are all isomorphic to  $C_2 \times C_2$ , and are all conjugate.

Proposition 4.1.7: Normal Groups of Order 30

Any group of order 30 has a nontrivial normal subgroup.

Definition 4.1.8: Simple Subgroup

A group  $G$  is **simple** if  $G$  has no nontrivial normal subgroups: that is, the only normal subgroups are  $\{e\}$  and  $G$  itself.

Lemma 4.1.9: Sylow Subgroups and Normal Groups

If a group  $G$  has a unique Sylow  $p$ -subgroup  $P$ , then  $P \triangleleft G$ .

Definition 4.2.1: Group Action

Let  $G$  be a group and  $X$  a set. An **action of  $G$  on  $X$**  is a function  $G \times X \rightarrow X, (g, x) \mapsto g \cdot x$  satisfying the following two properties:

- The identity acts trivially:  $e \cdot x = x$  for all  $x \in X$ .
- We have  $g \cdot (h \cdot x) = (gh) \cdot x$  for all  $g, h \in G$  and  $x \in X$ . (this is easiest to remember as a form of associativity.)

**Note:** We write our group actions as  $g \cdot x$ .

If $x \in X$ then the <b>orbit</b> of $x$ is	The <b>stabilizer</b> of $x$ is
$G \cdot x = \{g \cdot x \mid g \in G\}$	$\text{Stab}_G(x) = \{g \in G : g \cdot x = x\}$

Lemma 4.2.2: Orbits Partitions

Let  $G$  act on  $X$ .

- The action induces an equivalence relation  $\sim$  on  $X$  defined by:  $x \sim y$  iff there exists  $g \in G$  with  $g \cdot x = y$
- The equivalence classes of this equivalence relation are the orbits.
- The distinct orbits in  $X$  form a partition of  $X$  (each element of  $x$  is in exactly one orbit, distinct orbits have empty intersection.)

Lemma 4.2.3

Let  $G$  be a group that acts on a set  $X$ . For all  $x \in X$ , the stabilizer  $\text{Stab}_G(x)$  is a subgroup of  $G$ .

Example 4.2.A: Examples of Actions

**Example 4.2.4:** Let  $k$  be a field and let  $n$  be a positive integer. Let  $G = GL_n(k)$  and  $X = k^n$ . Then  $G$  acts on  $X$  via  $A \cdot v = Av$  that is, by matrix multiplication.

**Example 4.2.5:** Let  $n$  be a positive integer. Let  $G = S_n$  and let  $X = \{1, \dots, n\}$ . Then  $G$  acts on  $X$  via  $\sigma \cdot i = \sigma(i)$ .

Theorem 4.2.6: Orbit-Stabilizer Theorem

Let  $G$  be a finite group acting on a set  $X$ , and let  $x \in X$ . Then  $|G| = |\text{Stab}_G(x)| |G \cdot x|$

Example 4.2.A: Conjugacy Class

We will look at  $G$  ating on itself by **conjugation**

$$g \cdot a = gag^{-1}$$

Lets check this is a group action:  $e \cdot a = eae^{-1} = a$ , and  $g \cdot (h \cdot a) = g \cdot (hah^{-1}) = g(hah^{-1}g^{-1}) = gha(gh)^{-1} = (gh) \cdot a$

Orbits and stabilizers of elements of  $G$  under the conjugacy action: If  $a \in G$ , then  $\text{Stab}_G(a) = \{g \in G \mid gag^{-1} = a\}$

Since we can write  $gag^{-1} = a$  as  $ga = ag$ ,  $\text{Stab}_G(a)$  is the **centralizer**  $C_G(a)$  (the elements of  $G$  that commute with  $a$ ). The orbit of  $a$  is  $G \cdot a = \{gag^{-1} \mid g \in G\}$

This is the set of elements that are conjugate to  $a$ , or the **conjugacy class** of  $a$ . We will write the conjugacy class of  $a$  as  $\text{Cl}(a)$ .

Lemma 4.2.7: Conjugacy Class Divides

Let  $G$  be a finite group. For any  $a \in G$ , we have  $|G| = |C_G(a)| |\text{Cl}(a)|$

Thus,  $|C_G(a)|$  and  $|\text{Cl}(a)|$  divide  $|G|$ .

This can also be written with the index of  $C_G(a)$  in  $G$ :

$$|\text{Cl}(a)| = [G : C_G(a)]$$

### Definition 4.2.B: Class Equation

Since conjugacy classes are orbits of a group action, we obtain from Lemma 4.2.2, they partition  $G$ . This gives us the **class equation**: If  $G$  is a finite group, then there are elements  $a_1, \dots, a_n \in G$  s.t.

$$G = \text{Cl}(a_1) \sqcup \text{Cl}(a_2) \sqcup \dots \sqcup \text{Cl}(a_n)$$

It is more usual to write

$$|G| = |\text{Cl}(a_1)| + |\text{Cl}(a_2)| + \dots + |\text{Cl}(a_n)| \quad (2)$$

Note that this means that the class equation gives a writing  $|G|$  as the sum of integers dividing  $|G|$ .

### Definition 4.2.11: $p$ -group

Let  $p$  be a prime. A  **$p$ -group** is a group  $G$  such that each element has an order a power of  $p$ . If  $|G|$  is finite, then  $G$  is a  $p$ -group iff  $|G|$  is a power of  $p$ , by Cauchy's Theorem.

### Theorem 4.2.12: Nontrivial Centres of $p$ -groups

Recall the centre is the set

$$Z(G) = \{z \in G \mid zg = gz \text{ for all } g \in G\}$$

Let  $G$  be a nontrivial finite  $p$ -group. Then the centre  $Z(G) \neq \{e\}$

## 4.3 Proofs of Sylow Theorems

Not going to be proved here lol

### Lemma 4.3.1: Fixed Points of a $p$ -group

Let  $p$  be a prime and let  $G$  be a finite  $p$ -group acting on a finite set  $X$ . Then the number of fixed points in  $X$  is congruent to  $|X| \pmod p$

### Corollary 4.3.2:

Let  $|G| = p^m r$ , with  $p$  not dividing  $r$ . Let  $P$  be a Sylow  $p$ -subgroup the number of conjugates of  $P$ . By definition,  $P$  is normal iff it has a unique conjugate.

### Definition 4.3.3: Normalizer

Let  $G$  be a group and  $H \leq G$ . The **normalizer** of  $H$  is

$$N_G(H) = \{g \in G \mid gHg^{-1} = H\}.$$

### Lemma 4.3.4: Conjugates Something

Let  $G$  be a finite group.

- a) For any subgroup  $H \leq G$ , we have

$$[G : N_G(H)] = \text{the number of distinct conjugates of } H$$

- b) Let  $p \mid |G|$  and  $P$  be a Sylow  $p$ -subgroup of  $G$ . Then  $n_p = [G : N_G(P)]$

### Example 4.3.A: Sylows and Normalizers for $S_4$

Very long working

## 5 Finitely Generated Abelian Groups

### Example 5.1.1: Isomorphisms for Groups of Order 100

Suppose  $A$  is an abelian group with  $|A| = 100$ . Then,

- Since  $100 = 2^2 \cdot 5^2$ , there will be a (unique) Sylow 2-subgroup  $P$ , say, of order 4, and a unique Sylow 5-subgroup  $Q$ , say, of order 25.
- Any element in  $P \cap Q$  has order dividing 4 and also dividing 25; so  $P \cap Q = \{e\}$ .
- $PQ$  is a subgroup of  $A$  that contains  $P$ , and so has order divisible by 4, and contains  $Q$  and so has order divisible by 25
- Hence  $PQ$  has order at least 100 and so  $PQ = A$ . By Chapter 2, Ex10,  $A \cong P \times Q$

Thus, the possibilities for  $A$  are:

$$C_4 \times C_{25}, \quad C_2 \times C_2 \times C_{25}, \quad C_4 \times C_5 \times C_5, \quad C_2 \times C_2 \times C_5 \times C_5$$

### Theorem 5.1.3: Isomorphisms for Finite Groups

Suppose  $A$  is a finite abelian group of order  $n$ , and  $n = p_1^{s_1} p_2^{s_2} \dots p_t^{s_t}$ . Let  $A_{p_i}$  be the unique Sylow  $p_i$ -subgroup of  $A$ . Then

$$A \cong A_{p_1} \times A_{p_2} \times \dots \times A_{p_t}$$

That is,  $A$  is isomorphic to the direct product of its Sylow subgroups.

### Theorem 5.1.4: Cyclic Subgroups of Abelian Groups

Let  $A$  be an abelian group with  $|A| = p^n$  for some prime  $p$ . Then  $A$  is isomorphic to the direct product of cyclic subgroups of orders  $p^{c_1}, p^{c_2}, \dots, p^{c_s}$ , where  $e_1 \geq e_2 \geq \dots \geq e_s \geq 1$  and  $e_1 + e_2 + \dots + e_s = n$ . This product is unique up to reordering factors.

### Corollary 5.1.5: Fundamental Thm of Finite Abelian Groups i

Let  $A$  be a finite abelian group. Then  $A$  is a direct product of cyclic groups of prime power order. This product is unique up to reordering the factors.

### Theorem 5.1.6: Chinese Remainder Theorem

Let  $m, n$  be nonzero coprime integers, then  $C_{mn} \cong C_m \times C_n$ .

### Corollary 5.1.8: Fundamental Thm of Finite Abelian Groups ii

Any finite abelian group of order  $n$  can be written as a direct product of cyclic groups

$$C_{n_1} \times C_{n_2} \times \dots \times C_{n_s},$$

where  $n_i$  divides  $n_{i+1}$  for each  $i = 1, 2, \dots, s-1$  and  $n_1 n_2 \dots n_s = n$ . This product is unique up to reordering the factors.

### Example 5.1.7: Cyclic 100 via the CRT

Using the Chinese Remainder Theorem 5.0.6, we have:

$$C_4 \times C_{25} \cong C_{100}; \quad C_2 \times C_2 \times C_{25} \cong C_2 \times C_{50}$$

$$C_4 \times C_5 \times C_5 \cong C_5 \times C_{20}; \quad C_2 \times C_2 \times C_5 \times C_5 \cong C_{10} \times C_{10}$$

Therefore, an alternative list is:

$$C_{100}, \quad C_2 \times C_{50}, \quad C_5 \times C_{20}, \quad C_{10} \times C_{10}$$

### Definition 5.1.9: Exponent of a Finite Group

The **exponent**,  $e(G)$ , of a finite group is the least common multiple of the orders of the elements of  $G$ . Note that  $e(G) \leq |G|$  for any finite group  $G$ , by Lagrange.

### Lemma 5.1.11

Let  $A$  be a finite abelian group.  $A$  contains an element of order  $e(A)$ .

### Corollary 5.1.12

If  $A$  is a finite abelian group with  $e(A) = |A|$  then  $A$  is cyclic.

### Example 5.1.10: Example of an Exponent

The symmetric group  $S_3$  has elements of order 1, 2, and 3; so  $e(S_3) = 6$ . However, note that  $S_3$  has no element of order 6.

### Theorem 5.1.13: Cyclicity of Field Group

Let  $A$  be a finite subgroup of the multiplicative group  $K^* := K \setminus \{0\}$  of a field  $K$ . Then  $A$  is a cyclic group.

**Corollary 5.1.14:** The multiplicative group of nonzero elements of a finite field is cyclic.

### Definition 5.2.1: Modules of a Ring

Let  $R$  be a ring. An  **$R$ -module** is an abelian group  $(M, +)$  together with a mapping

$$R \times M \rightarrow M, \quad (r, a) \mapsto ra$$

that is **distributive**, **associative**, and **unital** ( $1a = a \forall a \in M$ ).

### Example 5.2.2: $\mathbb{Z}$ -module

A  $\mathbb{Z}$ -module is the same as an abelian group: if  $(M, +)$  is an abelian group,  $n \in \mathbb{Z}$ , and  $a \in M$  define

$$na = \begin{cases} \underbrace{a + a + \dots + a}_{n \text{ times}} & n > 0 \\ 0 & n = 0 \\ -(-n)a & n < 0 \end{cases}$$

### Example 5.2.3

If  $K$  is a field then a  $K$ -module is the same as a  $K$ -vector space.

### Definition 5.2.4: Free Module

Let  $R$  be a ring, and let  $n \in \mathbb{N}$ . The **free  $R$ -module of rank  $n$**  is the  $n$ -fold cartesian product  $R^n$ . It is given a module structure by

$$r(a_1, a_2, \dots, a_k) = (ra_1, ra_2, \dots, ra_k)$$

### Thm 5.2.5: FT of Finitely Generated Abelian Groups

Let  $A$  be a finitely generated abelian group. Then

$$A \cong \mathbb{Z}/r_1\mathbb{Z} \times \mathbb{Z}/r_2\mathbb{Z} \times \dots \times \mathbb{Z}/r_k\mathbb{Z} \times \mathbb{Z}^\ell$$

for some  $k, \ell \in \mathbb{N}$  and  $r_1, \dots, r_k$  nonzero elements of  $\mathbb{Z}$  with  $r_1 \mid r_2 \mid \dots \mid r_k$ .

### Lemma 5.2.6: Basis of $\mathbb{Z}$ -modules

Let  $\alpha$  be a  $\mathbb{Z}$ -module automorphism of  $\mathbb{Z}^s$ . Then  $\mathbb{Z}^s / K \cong \mathbb{Z}^s / \alpha(K)$ .

### Proposition 5.2.7:

Suppose that  $M$  is the  $r \times s$  matrix corresponding to  $K = \sum_{i=1}^r \mathbb{Z}x_i \subseteq \mathbb{Z}^s$ . If we change  $M \rightsquigarrow M'$  via invertible row and column operations then  $M'$  corresponds to a submodule  $K'$  of  $\mathbb{Z}^s$  so that  $\mathbb{Z}^s / K \cong \mathbb{Z}^s / K'$ .

### Useful Fact 5.3.1: Parity of Sequences

If  $x_1, x_2, x_3, \dots$  are a sequence of integers with  $x_i \mid x_{i-1}$  for all  $i$ , then there is  $n$  such that  $x_i = \pm x_{i+1}$  for all  $i \geq n$

### Proposition 5.3.2:

Let  $p$  be prime and let  $a_1 \geq a_2 \geq \dots \geq a_m$  and  $b_1 \geq b_2 \geq \dots \geq b_n$  be positive integers. If

$$A = C_{p^{a_1}} \times \dots \times C_{p^{a_m}} \cong B = C_{p^{b_1}} \times \dots \times C_{p^{b_n}}$$

then  $m = n$  and  $a_i = b_i$  for all  $1 \leq i \leq m$ .

6 Alternating Groups

Recall 6.1.A: Permutations

Recall the **symmetric group**  $S_n$  is the group of permutations (or bi-jections) of  $n$  objects. We usually think of the  $n$  objects as being the  $\begin{pmatrix} 1 & 2 & \cdots & n \\ \sigma(1) & \sigma(2) & \cdots & \sigma(n) \end{pmatrix}$  set  $\{1, 2, \dots, n\}$ . A permutation can be written as a  $2 \times n$  array (right).

For example, the following permutation denotes  $\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \end{pmatrix}$  the permutation that sends  $1 \mapsto 2, 2 \mapsto 4, 3 \mapsto 1,$  and  $4 \mapsto 3$ .

Recall  $\sigma\tau$  means  $\sigma \circ \tau$ ; i.e. first apply  $\tau$  and then apply  $\sigma$  to the result.

We usually write permutations using cycle notation. For example, the cycle  $(214)$  denotes the permutation that sends  $2 \mapsto 1, 1 \mapsto 4$  and  $4 \mapsto 2$ , where all other elements are fixed. Note that cycle notation doesn't give unique representations, e.g.  $(214) = (142) = (421)$ . In this notation, the above permutation would be written  $(1243)$ . A cycle is a  $k$ -cycle if it has  $k$  entries; so  $(214)$  is a 3-cycle, while  $(35)$  is a 2-cycle.

Two cycles are **disjoint** if no integer appears in both cycles. e.g.  $(214)(35)$  is a product of two disjoint cycles, and is the permutation  $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 1 & 5 & 2 & 3 \end{pmatrix}$

Note that two disjoint cycles commute; e.g.  $(214)(35) = (35)(214)$ . The product of non-disjoint cycles is not usually commutative; e.g.  $(214)(45) \neq (45)(214)$ , the first product sends 5 to 2 while the second sends 5 to 4.

Lemma 6.1.1: Unique Representation of Permutations

Every permutation can be written as a product of disjoint cycles, and the product is unique up to re-ordering the factors.

e.g. the following permutation is written as  $(142)(36)(5)$  in cycle, but could also be written  $(36)(5)(142)$   $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 4 & 1 & 6 & 2 & 5 & 3 \end{pmatrix}$

1-cycles are usually omitted, and it is taken that any number not appearing is fixed by the permutation; so for example, we would usually write the above permutation as  $(142)(36)$ .

A 2-cycle is often called a **transposition**, and a 2-cycle of the form  $(i\ i+1)$  is an **adjacent transposition**.

Lemma 6.1.2: Transposition Form

Every permutation can be written as a product of transpositions. Thus,  $S_n$  is generated by transpositions. In fact,  $S_n$  is generated by adjacent transpositions. Think bubble sort.

Definition 6.1.3: Cycle Type of a Permutation

Suppose that  $\sigma = c_1 c_2 \cdots c_k$  is a product of  $k$  disjoint cycles of length  $l_1, l_2, \dots, l_k$  with  $l_1 \geq l_2 \geq \cdots \geq l_k$ . Then the  $k$ -tuple  $(l_1, l_2, \dots, l_k)$  is called the **cycle type** of  $\sigma$ .

Example 6.1.5: Conjugate of Permutations

Let  $c = (125)$  and  $g = (23)(145)$  in  $S_5$ . A representation of  $g$  is shown to the right  $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 3 & 2 & 5 & 1 \end{pmatrix}$   
The conjugate  $gcg^{-1}$  is  $(23)(145)(125)(154)(23) = (143)(2)(5) = (431) = (g(1)g(2)g(5))$

Lemma 6.1.7: Conjugacy Formula

Let  $\sigma = (a_1\ a_2\ \cdots\ a_k) \in S_n$ , and  $\tau \in S_n$ . Then  $\tau\sigma\tau^{-1} = (\tau(a_1)\ \tau(a_2)\ \cdots\ \tau(a_k))$

Theorem 6.1.8: Conjugacy Equals Cycle Type

Two permutations in  $S_n$  are conjugate iff they have the same cycle type

Recall 6.2.A: Actions on Two Elements

We consider an action of  $S_n$  on a set of two elements. Let  $x_1, \dots, x_n$  be indeterminates, and set

$$P := \prod_{1 \leq i < j \leq n} (x_i - x_j)$$

Now, set  $X = \{P, -P\}$ . Then  $S_n$  acts on  $X$  by permuting the variables. For example, when  $n = 3$  then  $P = (x_1 - x_2)(x_1 - x_3)(x_2 - x_3)$  and  $(13)$  sends  $P$  to  $(x_3 - x_2)(x_1 - x_3)(x_2 - x_3) = -P$

Definition 6.2.1: Odd and Even Permutations

- If  $\sigma \in S_n$  fixes  $P$  then  $\sigma$  is an **even permutation**
- if  $\sigma \cdot P = -P$  then  $\sigma$  is an **odd permutation**
- The set of even permutations is the **alternating group**, or  $A_n$ .

Lemma 6.2.2: Products of Odd and Even Permutations

- The product of two even permutations is even
- The product of two odd permutations is even
- The product of an odd and an even permutation (either order) is odd
- A cycle of length  $n$  is even if  $n$  is odd and is odd if  $n$  is even.

Theorem 6.2.3: Even Permutations are a Subgroup

Let  $n \geq 2$ . Then the set of even permutations  $A_n$  is a normal subgroup of  $S_n$  of index 2; so that  $|A_n| = |S_n|/2 = n!/2$  for  $n \geq 2$ .

Proposition 6.2.4: Properties of  $A_4$

The alternating group  $A_4$  has order 12. It has a unique subgroup  $N$  of order 4. The subgroup  $N$  is normal in  $S_4$  (and so certainly  $N \triangleleft A_4$ ) and  $A_4/N \cong C_3$ , while  $S_4/N \cong S_3$ .

Lemma 6.2.5: Closure Union

Let  $G$  be a finite group and suppose that  $H \triangleleft G$ . Then there are  $h_1, \dots, h_k \in H$  so that  $H = \bigsqcup \text{Cl}_G(h_i)$ .

Theorem 6.3.A: Simple Alternating Groups

- 6.3.1)** The alternating group  $A_5$  is simple.
- 6.3.3)** Let  $n \geq 5$ . Then  $A_n$  is simple.
- 6.3.4)** If  $n \geq 5$  and  $\sigma, \sigma'$  are 3-cycles in  $A_n$ , then  $\sigma$  and  $\sigma'$  are conjugate in  $A_n$ : that is, there exists  $\tau \in A_n$  with  $\tau\sigma\tau^{-1} = \sigma'$
- 6.3.5)** If  $n \geq 3$ , then  $A_n$  is generated by 3-cycles.
- 6.3.6)** If  $H \leq S_n$  and  $H$  has the property that any  $\sigma \in H$  with  $\sigma \neq ()$  is fixed-point-free, then  $|H| \leq n$ .
- 6.3.7)** If  $n \geq 6$  and  $\sigma \in A_n$  with  $\sigma \neq ()$ , then  $|\text{Cl}_{A_n}(\sigma)| \geq n$ .

7 Jordan H\"older Theorem

Example 7.1.1: Composition Series

Consider the chains of normal subgroups  $\{0\} \triangleleft 4\mathbb{Z}/12\mathbb{Z} \triangleleft 2\mathbb{Z}/12\mathbb{Z} \triangleleft \mathbb{Z}/12\mathbb{Z}$   
 $\{0\} \triangleleft 6\mathbb{Z}/12\mathbb{Z} \triangleleft 3\mathbb{Z}/12\mathbb{Z} \triangleleft \mathbb{Z}/12\mathbb{Z}$

These are both examples of **composition series**

Definition 7.1.2: Composition Series

For a group  $G$ , a **composition series** for  $G$  is a chain of subgroups  $\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_{s-1} \triangleleft G_s = G$  (\*) where  $G_i \neq G_{i+1}$  and  $G_{i+1}/G_i$  is simple for all  $i$ . If (\*) is a composition series for  $G$ , we say that  $s$  is the **length** of the composition series and the simple groups  $G_{i+1}/G_i$  are the **composition factors**.

Theorem 7.1.3: Jordan H\"older Theorem

Let  $G$  be a finite group. Then  $G$  has a composition series. Moreover, any two composition series have the same composition length, and they have the same composition factors up to isomorphism of groups and order of the factors.

Theorem 7.1.4: Classification of Finite Simple Groups

Let  $G$  be a finite simple group. Then  $G$  is isomorphic to one of:  
• **Family 1:**  $C_p$  for  $p$  prime  
• **Family 2:**  $A_n$  for  $n \geq 5$   
• 16 other infinite families  
• 26 sporadic groups.

Proposition 7.2.1: Finite Composition Series

If  $G$  is a finite group, then  $G$  has a composition series.

Sublemma 7.2.2

Let  $\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_{s-1} \triangleleft G_s = G$  be a composition series for  $N$ , and  $N = H_0 \triangleleft H_1 \triangleleft \cdots \triangleleft H_r = G/N$  be a composition series for  $G/N$ . Then there is a composition series for  $G$  of length  $s + r$ , whose composition factors are, in order,  $G_1, G_2/G_1, \dots, G_s/G_{s-1}, H_1, H_2/H_1, \dots, H_r/H_{r-1}$

Theorem 7.3.1: Composition Factors of Series

Let  $G$  be a finite group. Then any two composition series have the same length and the same composition factors up to isomorphism and the order in which they are listed. More precisely, if

$$\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_{s-1} \triangleleft G_s = G \tag{†}$$

and

$$\{e\} = H_0 \triangleleft H_1 \triangleleft \cdots \triangleleft H_{r-1} \triangleleft H_r = G \tag{‡}$$

are two composition series for  $G$ , then  $s = r$  and there is a permutation  $\sigma$  of  $\{0, \dots, s - 1\}$  s.t.  $H_{i+1}/H_i \cong G_{\sigma(i)+1}$ , for all  $i = 0, \dots, s - 1$ .

Definition 8.1.1: Subnormal Series

Let  $G$  be a group. A **subnormal series** for  $G$  is a series of subgroups

$$\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_s = G$$

**Warning:** normality is not transitive. That is, there exists  $C$  with subgroups  $A \triangleleft B \triangleleft C$  where  $A$  is not a normal subgroup of  $C$ .

Definition 8.1.2: Solvable Group

A group  $G$  is **solvable/soluble** provided that it has a subnormal series

$$\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_s = G$$

such that each factor  $G_{i+1}/G_i$  is abelian.

Example 8.1.3: Examples of Solvable Groups

- a)  $S_3$  is not abelian, but is solvable, as the subnormal series  $\{e\} \triangleleft A_3 \triangleleft S_3$  demonstrates.
- b)  $S_4$  is solvable.
- c)  $A_5$  is not solvable: as it is a simple group, its only subnormal series is  $\{e\} \triangleleft A_5$  and the only factor is  $A_5$  which is not abelian.
- d) Any finite  $p$ -group is solvable. Let  $|G| = p^k$ , where  $p$  is prime.  $G$  has a subnormal series  $\{e\} = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_k = G$ , where  $|G_i| = p^i$ . Since each  $G_i/G_{i-1}$  has order  $p$ , it is abelian.

Theorem 8.1.4: Solvable Cyclic Groups

A finite group  $G$  is solvable iff all composition factors of  $G$  are cyclic.

### Lemma 8.1.5: Composition Factors for FA Groups

If  $A$  is a finite abelian group of order  $p_1^{n_1} p_2^{n_2} \cdots p_k^{n_k}$ , then the composition factors of  $A$  are

$$\underbrace{C_{p_1}, \dots, C_{p_1}}_{n_1}, \underbrace{C_{p_2}, \dots, C_{p_2}}_{n_2}, \dots, \underbrace{C_{p_k}, \dots, C_{p_k}}_{n_k}$$

in some order.

### Theorem 8.1.A: Solvable Properties

- 8.1.6)** Let  $G$  be a group and let  $N \triangleleft G$ . Then  $G$  is solvable iff both  $N$  and  $G/N$  are solvable.
- 8.1.7)** If  $G$  is solvable and  $H \leq G$  then  $H$  is solvable.
- 8.1.9)** There is no quintic formula.

### Definition 8.2.1: Commutators and Derived Subgroups

Let  $G$  be a group. The **commutator** of two elements  $a, b \in G$  is the element  $aba^{-1}b^{-1}$ , and is often denoted by  $[a, b]$ .

The **derived subgroup** (or **commutator subgroup**)  $G'$  of a group  $G$  is the subgroup generated by all possible commutators in  $G$ ; that is,

$$G' := \langle aba^{-1}b^{-1} \mid a, b \in G \rangle$$

**Remark:** Some properties of the commutator subgroup:

- $[a, b]^{-1} = [ba]$  and the conjugate of  $[a, b]$  by  $z$  is  $[zaz^{-1}, zbz^{-1}]$ . Thus, inverses and conjugates of commutators are commutators
- Every element in  $G'$  is a product of commutators
- $G' \triangleleft G$
- The product of two commutators is not necessarily a commutator

### Theorem 8.2.2: Commutators and Abelian Groups

Let  $G$  be a group and  $N$  a normal subgroup of  $G$ . Then  $G/N$  is abelian iff  $G' \subseteq N$ . In particular,  $G/G'$  is abelian.

### Definition 8.2.3: Derived Series

Let  $G$  be a group. Set  $G^0 = 0$  and for each  $i \geq$ , set  $G^{(i+1)} := (G^{(i)})'$ . The sequence

$$G = G^{(0)} \triangleright G^{(1)} \triangleright G^{(2)} \triangleright \cdots$$

is called the **derived series** of  $G$ . (Note that  $G^{(1)} = G'$ )

**Remark:** Some properties of derived series:

- If there is an  $i$  s.t.  $G^{(i+1)} = G^{(i)}$  then  $G^{(j)} = G^{(i)}$  for all  $j \leq i$ .
- If  $G$  is a finite group, then there must be an  $i$  s.t.  $G^{(i+1)} = G^{(i)}$ . However, this may happen without it being the case  $G^{(i)} = \{e\}$
- Let  $G = A_5$ . Then  $G^{(1)} \triangleleft G$  and so  $G^{(1)} = \{e\}$  or  $G^{(1)} = G$ , as  $G$  is simple. However,  $G/G^{(1)}$  is abelian, and so  $G^{(1)} = \{e\}$  is impossible, as  $G = A_5$  is not abelian. Thus,  $G^{(1)} = G$  and so  $G^{(i)} = G$ ,  $\forall i \geq 1$ . (this works for any non-abelian simple group)
- If  $G^{(n)} = \{e\}$  for some  $n$  then the series

$$G = G^{(0)} \triangleright G^{(1)} \triangleright G^{(2)} \triangleright \cdots \triangleright G^{(n)} = \{e\}$$

has abelian factors  $G^{(i)}/G^{(i+1)}$ , since  $G^{(i)}/G^{(i+1)} = G^{(i)}/(G^{(i)})'$ . Thus,  $G$  is solvable.

### Theorem 8.2.4: Solvability with Derived Groups

A group  $G$  is solvable iff there is an  $n$  with  $G^{(n)} = \{e\}$ .

### Definition 8.2.5: Derived Length

Let  $G$  be a solvable group. Then  $G^{(n)} = \{e\}$  for some  $n$ . The least such  $n$  is the **derived length** of  $G$ .

## 8 Library of Groups

### Example 8.1.1: Group Presentations

**Dihedral Group  $D_n$ .**

- Presentation:  $D_n = \langle g, h \mid g^n, h^2, (gh)^2 \rangle$

**Conjugacy classes for Dihedral Group  $D_7$**

Element	Centralizer	Conjugacy Class	CCs
$\{e\}$	$D_n$	$\{e\}$	1
$\{g^k, g^{k-n}\}$	$\{e, g, \dots, g^n\}$	$\{g^k, g^{n-k}\}$	$2 \cdot 3$
$\{h, hg, \dots, hg^{k-n}\}$	$\{hg^k, hg^{n-k}\}$	$\{hg^k \dots hg^{n-k}\}$	$7 \cdot 1$

**Cyclic Group  $C_n$**

- Presentation:  $C_n = \langle a \mid a^n \rangle$
- Cyclic (clearly), abelian
- Simple if prime order.
- Solvable if  $n < 60$  via cyclic composition factors.

**Symmetric Group  $S_3$**

- Not abelian
- SG:  $\{e\}, \{e, (2, 3)\}, \{e, (1, 3)\}, \{e, (1, 2)\}, A_3 := \{e, (123), (132)\}$
- Normal SGs:  $\{e\}, A_3, S_3$
- Solvable from the subnormal series  $\{e\} \triangleleft V_4 \triangleleft A_3 \triangleleft S_3$ .
- Counterexample CS:  $\{e\} \triangleleft C_2 \triangleleft A_3 \triangleleft S_3$  but  $C_2 \ntriangleleft S_3$
- Conjugacy classes:  $6 = 1 + 2 + 3$ , exactly the ones of same cycle type.  
 $\{e\}, \{(12), (13), (23)\}, \{123, 132\}$

**Alternating Group  $A_4$**

- Order 12, Not abelian ( $(123)$  and  $(12)(34)$  don't commute)
- Solvable, length 2, derived subgroup is  $\mathbb{Z}_2 \times \mathbb{Z}_2$ .
- SG:  $\{e\}, \mathbb{Z}_2, \mathbb{Z}_2 \times \mathbb{Z}_2, A_3$
- Conjugacy classes:  $12 = 1 + 3 + 4 + 4$

$$\{e\}, \{(12)(34), (13)(24), (14)(23)\}, \\ \{(123), (243), (143), (142)\}, \{(132), (234), (143), (124)\}$$

**Alternating Group  $A_5$**

- Order 60, Smallest simple non-abelian group  $(123)$  and  $(12345)$
- Not solvable, as  $n \geq 5$  (7.1.3)

Other Presentations

- Product Group**  $\mathbb{Z} \times \mathbb{Z} = \langle x, y \mid xy = yx \rangle$  or  $\langle x, y \mid xyx^{-1}y^{-1} \rangle$
- Free Group**:  $\langle x \mid - \rangle$
- Klein 4**:  $V_4 \cong D_2 \cong C_2 \times C_2 = \langle x, y \mid x^2, y^2, (xy)^2 \rangle$ .
- Quaternion**:  $Q_8 = \langle i, j \mid i^4, j^2, j^2 = i, j^2 = j \rangle$
- Tits group**:  $\langle a, b \mid a^2, b^3, (ab)^{13}, [a, b]^5, [a, bab]^4, ((ab)^4 ab^{-1})^6 \rangle$

### Definition 8.1.2: Group Properties

- Kernel**:  $\{g \in G \mid \phi(g) = e\}$  for some homomorphism  $\phi$ .  $\ker \phi = e$  implies injective.
- Stabilizer (under conj.)**:  $\text{Stab}_G(a) = \{g \in G \mid gag^{-1} = a\}$ . under conjugation this is the **centralizer**,  $C_G(a)$ .
- Orbit (under conj.)**:  $G \cdot a = \{gag^{-1} \mid g \in G\}$ . Under conjugation, these are the **conjugacy classes**,  $\text{Cl}(a)$ .
- p-group**: A group where each element has order a power of  $p$ . If  $|G|$  finite,  $p$ -group iff  $|G|$  is a power of  $p$ .
- Normalizer**:  $N_G(H) = \{g \in G \mid gHg^{-1} = H\}$ .
- Centre**:  $Z(G) = \{z \in G \mid zg = gz \text{ for all } g \in G\}$ . The centre is nontrivial for nontrivial finite  $p$ -groups
- Normal**:  $H \triangleleft G$  if  $gH = Hg$ , or  $gHg^{-1} := \{gHg^{-1} \mid h \in H\} = H$  for all  $g \in G$

9 Examples

Example 4.1.7: Normal Subgroups of Order 30 Groups

Prop 4.1.7: Any group of order 30 has a nontrivial normal subgroup.

*Proof.* Let  $G$  be a group of order  $30 = 2 \cdot 3 \cdot 5$ . By Sylow III (4.1.2),

$$n_5 \mid 6 \text{ and } n_5 \equiv 1 \pmod{5}, \quad n_3 \mid 6 \text{ and } n_3 \equiv 1 \pmod{3}$$

Thus there is either a Unique Sylow 5-subgroup of  $G$  (order 5), or there are 6 Sylow 5-subgroups. Likewise we have either a unique Sylow 3-subgroup (order 3) or there are 10.

Suppose  $n_3 = 10$  and  $n_5 = 6$ . Let the Syl-5 of  $G$  be  $P_1, \dots, P_6$ . If  $i \neq j$  then  $P_i \cap P_j$  is a subgroup of  $P_i$  (and  $P_j$ ) that is not all of  $P_i$ . Since  $|P_i|$  is prime, by Lagrange  $P_i \cap P_j = \{e\}$ . Each  $P_i$  has 4 elements of order 5, so  $\bigcup_{i=1}^6 P_i$  is  $e$  and 24 elements of order 5.

Likewise Let the Syl-3 of  $G$  be  $Q_1, \dots, Q_{10}$ . Same process to reach  $\bigcup_{i=1}^{10} Q_i$  consists of  $e$  and 20 elements order 3. However  $|G| = 30$  so either Sylow-3 unique or Sylow-5 unique

Suppose  $n_5 = 1$ . Let  $P$  be the unique subgroup of order 5 and let  $g \in G$ . Then  $gPg^{-1}$  is also a subgroup of order 5 and therefore  $gPg^{-1} = P$ , i.e.  $P \triangleleft G$ . Same conclusion for if  $n_3 = 1$ . □

Example B: Correspondence

Let  $G$  be a group of order  $5^2 \cdot 3^2 \cdot 17$  with a normal subgroup  $S$  order 5 with a NSG  $S$  order 5, and suppose  $G/S$  is abelian. Suppose  $G$  has an element of order 9, find the number of subgroups of  $G$  with order  $5 \cdot 3 \cdot 17$  that contain  $S$ .

*Proof.* Take the (abelian) factor group  $G/S$ , which has order  $5 \cdot 3^2 \cdot 17$  (as  $|S| = 5$ ). The Correspondence Theorem states that there is a bijection between subgroups of  $G$  containing  $S$ , and subgroups of  $G/S$ . Therefore we want to find the number of subgroups of order  $3 \cdot 17$  in  $G/S$ , such that they map back up to a subgroup order  $3 \cdot 5 \cdot 17$  in  $G$ . There is one subgroup of this nature in  $G/S$  up to isomorphism, namely  $C_3 \times C_{17}$ , therefore via the correspondence theorem, there is one subgroup with order  $5 \cdot 3 \cdot 17$  in  $G$ , namely  $C_5 \times C_3 \times C_{17}$  □

Let  $G$  be a group of order  $196 = 4 \cdot 49$ . show  $G$  has a proper normal subgroup with even cardinality.

*Proof.* We have  $n_7 \mid 4$  and  $n_7 \equiv 1 \pmod{7}$ , therefore unique Sylow 7-subgroup, which is normal.  $G/P$  has order  $4 = 2^2$  therefore abelian. By Cauchy,  $G/P$  contains a subgroup  $H$  of order 2 which must be normal as  $G/P$  is abelian. Via correspondence,  $\text{can}^{-1}(H)$  is then a normal subgroup of order  $2 \times 49$  in  $G$ . □

Example C: Presentation

$$G = \langle x, y \mid x^4, y^3, xyx \rangle$$

We have  $x^4 = xyx \implies x^3 = xy \implies x^2 = y$ . Substitute in  $x^2 = y$ :

$$\begin{aligned} G &= \langle x, y \mid x^4, y^3, xyx \rangle \\ &= \langle x \mid x^4, x^6, x^4 \rangle \\ &= \langle x \mid x^2 \rangle \end{aligned}$$

Therefore isomorphic to  $C_2$

Example D: Multiplied Orders

Find an Abelian group of order 2000 where  $20A$  has order 10.

$$g^{20} \mid g \in A$$

*Proof.* WTS: Iso Product of 2000 where the prime factors make 10

$$\mathbb{Z}_8 \times \mathbb{Z}_{25} \times \mathbb{Z}_{10}$$

has  $\text{GCD}(8, 20) = 4$  and  $8/4 = 2$ ,  $\text{GCD}(25, 20) = 5$  and  $25/5 = 5$ ,  $\text{GCD}(10, 20) = 10$  and  $10/10 = 1$  therefore  $2 \cdot 5 \cdot 1$  so the generator has order 10. □

Example E: Presentation Homomorphism

Consider  $D_5$ , and  $E = \langle a, b \mid a^2, b^5, (ab)^2 \rangle$ . Consider

$$\phi : \langle A, B \rangle \rightarrow D_5, \quad A \mapsto g, \quad B \mapsto h$$

$A^2, B^5$ , and  $(AB)^2$  are in  $\ker \psi$ . These elements are also in  $\ker \pi$ , from the relations on  $E$ .  $\ker \pi$  is equal to the set of words in  $\langle A, B \rangle$  that become equal to  $e$  as a logical consequence of (the group axioms and) setting  $A^2, B^5, (AB)^2 = e$ . i.e.  $\ker \pi$  is equal to the set of words in  $\langle A, B \rangle$  that become equal to  $e$  by any group homomorphism from  $\langle X, Y \rangle$  to a group  $K$  that sends  $A^2, B^5, (AB)^2$  to  $e$ . All these logical consequences must also be in  $\ker \psi$ . However we don't know if we have found all relations of  $D_5$ , i.e. maybe some word in  $\ker \psi$  that is not in  $\ker \pi$ . i.e. we have homomorphisms

$$\begin{array}{ccc} \langle A, B \rangle & \xrightarrow{\pi} & E \\ & \searrow \psi & \\ & & D_5 \end{array}$$

and also  $\ker \pi \subseteq \ker \psi$ . The Universal prop of factor groups applies, therefore we have  $\bar{\psi} : E \rightarrow D_5$  s.t.  $\bar{\psi}\pi = \psi$ :

$$\begin{array}{ccc} \langle A, B \rangle & \xrightarrow{\pi} & E \\ & \searrow \psi & \downarrow \bar{\psi} \\ & & D_5 \end{array}$$

In particular,  $\bar{\psi}(a) = g$  and  $\bar{\psi}(b) = h$ . So  $\bar{\psi}$  is surjective and  $|E| \geq |D_5| = 10$ . But  $|E| \leq 10$ . So  $|E| = 10$  and  $\bar{\psi}$  is iso.
